A practical methodology for designing integrated automation control for systems and processes Implementing digital control within mechanical-electronic (mechatronic) systems is essential to respond to the growing demand for high-efficiency machines and processes. In practice, the most efficient digital control often integrates time-driven and event-driven characteristics within a single control scheme. However, most of the current engineering literature on the design of digital control systems presents discrete-time systems and discrete-event systems separately. Control Of Mechatronic Systems: Model-Driven Design And Implementation Guidelines unites the two systems, revisiting the concept of automated control by presenting a unique practical methodology for whole-system integration. With its innovative hybrid approach to the modeling, analysis, and design of control systems, this text provides material for mechatronic engineering and process automation courses, as well as for self-study across engineering disciplines. Real-life design problems and automation case studies help readers transfer theory to practice, whether they are building single machines or large-scale industrial systems. Presents a novel approach to the integration of discrete-time and discrete-event systems within mechatronic systems and industrial processes Offers user-friendly self-study units, with worked examples and numerous real-world exercises in each chapter Covers a range of engineering disciplines and applies to small- and large-scale systems, for broad appeal in research and practice Provides a firm theoretical foundation allowing readers to comprehend the underlying technologies of mechatronic systems and processes Control Of Mechatronic Systems is an important text for

In recent decades, the development of computer-controlled manufacturing by adding material layer by layer, called Additive Manufacturing (AM), has developed at a rapid pace. The technology adds possibilities to the manufacturing of geometries that are not possible, or at least not economically feasible, to manufacture by more conventional manufacturing methods. AM comes with the idea that complexity is free, meaning that complex geometries are as expensive to manufacture as simple geometries. This is partly true, but there remain several design rules that need to be considered before manufacturing. The research field Design for Additive Manufacturing (DfAM) consists of research that aims to take advantage of the possibilities of AM while considering the limitations of the technique. Computer Aided technologies (CAx) is the name of the usage of methods and software that aim to support a digital product development process. CAx includes software and methods for design, the evaluation of designs, manufacturing support, and other things. The common goal with all CAx disciplines is to achieve better products at a lower cost and with a shorter development time. The work presented in this thesis bridges DfAM with CAx with the aim of achieving design automation for AM. The work reviews the current DfAM process and proposes a new integrated DfAM process that considers the functionality and manufacturing of components. Selected parts of the proposed process are implemented in a case study in order to evaluate the proposed process. In addition, a tool that supports part of the design process is developed. The proposed design process implements Multidisciplinary Design Optimization (MDO) with a parametric CAD model that is evaluated from functional and manufacturing perspectives. In the implementation, a structural component is designed using the MDO framework, which includes Computer Aided Engineering (CAE) models for structural evaluation, the calculation of weight, and how much support material that needs to be added during manufacturing. The component is optimized for the reduction of weight and minimization of support material, while the stress levels in the component are constrained. The developed tool uses methods for high level Parametric CAD modelling to simplify the creation of parametric CAD models based on Topology Optimization (TO) results. The work concludes that the implementation of CAx technologies in the DfAM process enables a more automated design process with less manual design iterations than traditional

DfAM processes. It also discusses and presents directions for further research to achieve a fully automated design process for Additive Manufacturing.

Offering a modern, process-oriented approach emphasizing process control scheme development instead of extended coverage of LaPlace space descriptions of process dynamics, this text focuses on aspects that are most important for process engineering in the 21st century. Instead of starting with the controller, the book starts with the process and moves on to how basic regulatory control schemes can be designed to achieve the process' objectives while maintaining stable operations. In addition to continuous control concepts, process and control system dynamics are embedded into the text with each new concept presented. The book also includes sections on batch and semi-batch processes and safety automation within each concept area. It discusses the four most common process control loops—feedback, feedforward, ratio, and cascade—and discusses application of these techniques for process control schemes for the most common types of unit operations. It also discusses more advanced and less commonly used regulatory control options such as override, allocation, and split range controllers, includes an introduction to higher level automation functions, and provides guidance for ways to increase the overall safety, stability, and efficiency for many process applications. It introduces the theory behind the most common types of controllers used in the process industries and also provides various additional plant automation-related subjects.

Process Automation Systems' design, selection, planning and implementation play a contributing role in achieving success in Industrial Megaprojects within the Oil and Gas Industry. Process Automation Systems represent only 8% - 10% of the total installed cost in capital projects, but the reliability and performance of Process Automation Systems are fundamental factors to ensure the operability and safety of new plants within the oil and gas industry. Recent studies show an increasing number of Industrial Megaprojects in execution during the last decade, a better understanding of the real impact that these projects can bring to our societies, the complexity of these endeavors and the likelihood of having more megaprojects being approved during the next 20 years in the global market. It is pleasant to hear that there are favorable conditions present in the industry to promote and execute capital projects, but there is an alarming rate at which these capital projects overrun schedules and budgets. Project execution key performance indicators such as cost growth, cost index, schedule index, schedule slippage and operability index often applied to measure the success of Megaprojects, should be carefully followed by project management teams, during the implementation of Process Automation Systems. In the oil and gas industry megaprojects are executed in a stage gated work process typically divided into phases with a pause for assessment and decision about whether to proceed. The gate assessments examine both economic/business and technical aspects of the project, to make decisions to stop, recycle or proceed. The purpose of this research is to identify practices in a stage gated work process approach (FEL Front End Loading) to increase the probability of success in Process Automation Systems implementation given complexity factors in Industrial Megaprojects.

Embedded systems now include a very large proportion of the advanced products designed in the world, spanning transport (avionics, space, automotive, trains), electrical and electronic appliances (cameras, toys, televisions, home appliances, audio systems, and cellular phones), process control (energy production and distribution, factory automation and optimization), telecommunications (satellites, mobile phones and telecom networks), and security (e-commerce, smart cards), etc. The extensive and increasing use of embedded systems and their integration in everyday products marks a significant evolution in information science and technology. We expect that within a short timeframe embedded systems will be a part of nearly all equipment designed or manufactured in Europe, the USA, and Asia. There is now a strategic shift in emphasis for embedded systems designers: from simply achieving feasibility, to achieving optimality. Optimal design of embedded systems means targeting a given market segment at the lowest cost and delivery time possible. Optimality implies seamless integration with the physical and electronic environment while respecting real-world constraints such as hard deadlines, reliability, availability, robustness, power consumption, and cost. In our view, optimality can only be achieved through the emergence of embedded systems as a discipline in its own right.

All-embracing manufacturing is a system that aims to dissolve the complexity of the manufacturing process and restore the inherent simplicity. It claims that production is very simple and flexible by nature. However, the complexity is a result of the production system approach which makes it rigid and therefore complex. All-embracing manufacturing introduces flexibility to production planning, it eliminates constraints, bottlenecks, and disruptions automatically while it restores the simplicity. No decision is

made ahead of time, but only at the time of execution. It introduces technology as dominant part of manufacturing. It is a computer oriented system that imitates human behavior i.e. practically as any of us behave in daily personal life.

Industrial automation systems are complex control systems that perform control and automation of hazardous plants. Safety of such systems is of paramount importance and may even be mandated by law. Safety-related systems may be required to demonstrate conformance to an applicable functional safety standards to assure safety and demonstrate that these systems mitigate the risk to human lives, as much as reasonably possible. IEC 61508 is a standard of functional safety for generic electric, electronic, and programmable electronic (E/E/PE) systems and is used as the principal guide in this thesis. IEC 61508 adopts a two-pronged approach for addressing random failures in the hardware and systematic errors in the software. Random failures are addressed using quantitative techniques for reliability analysis e.g., reliability block diagrams and Markov analysis, and by computing the safe failure fraction to establish a confidence level. Systematic errors, on the other hand, are avoided by following quality assurance recommendations and qualitative validation techniques. However, this segregated application of quantitative and qualitative approaches is inadequate for addressing complexities introduced by software-intensive control systems. Furthermore, the manual application of traditional safety analysis techniques is tedious, error-prone, and largely dependent on practitioners' skills. In order to ameliorate these problems, a model-driven approach towards safety analysis named, model-based safety assessment (MBSA) was proposed, which has gained significant interest in academia and industry in the recent years. MBSA approaches use system models for the purpose of safety analysis such as extracting fault trees, performing quantitative analysis, or discovering a critical sequence of errors that may cause system failures. MBSA can be performed on either by using dedicated safety models or by using system development models. The latter approach allows seamless integration with model-driven development (MDD), which is the state-of-the-art for design, implementation and validation of control and automation systems. In MDD, high-level system models are constructed that are iteratively refined by adding details until an implementation of the system software can be automatically extracted from the development models using automatic code generation. One such approach for implementing industrial control systems uses IEC 61499, which is an open standard for implementing industrial process controller and measurement systems. It proposes various design artefacts e.g., basic and composite function blocks and enables a component-oriented design approach for implementing complex behaviours i.e., by connecting function blocks to form function block networks. A popular design pattern for the development of IEC 61499 based systems suggests the implementation of two separate tiers called plant-model and controller. The plantmodel mimics the expected behaviour of the plant and the controller implements the automation

logic. When connected in a closed-loop, the overall system model is formed that is used for various verification and validation activities such as formal verification, testing, simulation. Such analyses are well-suited for safety-critical systems and help to avoid systematic errors. However, plant-models are also susceptible to random errors, which cannot be analysed by using qualitative techniques alone. Unfortunately, all existing validation and verification techniques available for IEC 61499 based systems are qualitative in nature, which cannot be used for the purpose of quantitative risk assessment. This calls for developing an approach for the quantitative safety assessment of IEC 61499 based systems. In this thesis, we present an MBSA approach for quantitative risk assessment of industrial automation systems using IEC 61499. The presented approach proposes a novel structure named stochastic function block for modelling stochastic aspects of random failures and environmental non-determinism in the plant-model. The controller, on the other hand, is developed using standard IEC 61499 function blocks. The overall system model is transformed into Markov decision processes in the Prism language for probabilistic verification using the Prism model checker. This enables quantitative analysis of the system behaviour presuming software behaviour under random errors of the plant. The controller is eventually used for automatic code generation and deployment onto the physical plant. Use of standard function blocks for the controller renders the proposed technique compliant to the IEC 61499 standard and permit seamless integration into the MDD activities. The key contributions of the presented work are as following. 1) A novel structure based on IEC 61499 basic function blocks named stochastic function block. This structure is used for representing the random errors in the plant model and environmental non-determinism. 2) A rule-based transformation from IEC 61499 function blocks to Prism model that preserves the adopted synchronous execution semantics. The generated Prism model is a Markov decision process that represents the probabilistic and non-deterministic aspects of the system due to its random errors. 3) A scalable MBSA approach for a unified qualitative and quantitative analysis, which is useful in the early design validation and managing modifications in system design. 4) An MDE tool-chain named BlokIDE, which provides support for the proposed stochastic function blocks and automatic translation to the Prism language. This enables stochastic error modelling and integration with the Prism model checker for the purpose of proposed MBSA approach. 5) A proposal for conforming to IEC 61508 requirements using IEC 61499 modelbased approach, showing various specification and design various stages of the V-Model. To the best of our knowledge, the proposed approach is the very first attempt for providing a model-based safety assessment approach for industrial automation systems using IEC 61499 along with a comprehensive tool-chain.

comparative approach to the models derived in this way judging their suitability for use in different systems and under different operational circumstances. A broad spectrum of control methods including various forms of filtering, feedback and feedforward control is applied to the models and the guidelines derived from the closed-loop responses are then composed into a concrete self-tested recipe to serve as a check-list for industrial engineers or control designers. System identification and control design are given equal weight in model derivation and testing to reflect their equality of importance in the proper design and optimization of high-performance control systems. Readers' assimilation of the material discussed is assisted by the provision of problems and examples. Most of these exercises use MATLAB® to make computation and visualization more straightforward. Applied Control System Design will be of interest to academic researchers for its comparison of different systems models and their response to different control methods and will assist graduate students in learning the practical necessities of advanced control system design.
